Translation from: Referativnyy zhurnal, Metallurgiya, 1958, Nr 6, p 64 (USSR)

AUTHORS: Rabinovich, A.G., Terekhova, V.S.

TITLE: The Influence of the Rate of Decarburization of the Metal Bath During the Working Period on the Saturation of the Metal with Gas (Vliyaniye skorosti obezuglerozhivaniya metallicheskoy vanny v period dovodki na gazonasyshchennost' metalla)

PERIODICAL: Byul. nauchno-tekhn. inform. Ukr. n.-i. in-t metallov, 1957, Nr 3 pp 22-32

ABSTRACT: Results are adduced for 70 heats run in 125-, 185-, and 370-t furnaces at the im. Kirov, Stalinsk, and im. Dzerzhinskiy plants. [H] was determined by the method of vacuum heating on the LPI apparatus [Morozov, A.N., Vodorod i azot v stali (Hydrogen and Nitrogen in Steel), Metallurgizdat, 1950]. It was found that absorption of H by metal declines as  $V_c$  rises during the period of boil. However, before deoxidation, [H] does not depend upon  $V_c$ . The absence of such a relationship is explained by the fact that as the metal temperature rises at the outset of the period of pure boil, there is an increase in [H] at that moment and an increase in  $V_c$  during the period of pure boil. This

Card 1/2

137-58-6-11673

• The Influence of the Rate (cont.)

inhibits further increase in  $[H]$ . The dilution of the slag at the end of a finishing period also results in an increase in  $[H]$ , but further increase in  $[H]$  will be inhibited by a higher  $V_c$ . When metal is deoxidized in a furnace,  $[H]$  rises and then declines on tapping and teeming. Therefore, all deoxidation of flake-sensitive grades of steel should be done in the ladle. High  $V_c$  is attained either through high  $FeO$ , or through an increase in temperature, etc. Therefore,  $V_c$  has a contradictory effect upon  $[O]$ . There is a direct relationship between  $[O]$  and  $[FeO]$ .

TITLE: Conference on new trends in the study and applications of rare-earth metals (Held at Moscow, 18-20 March 1963)

SOURCE: AN SSSR. Izv. Otd. tekhnicheskikh nauk. Metallurgiya i gornoye delo, no. 3, 1963, 191-192

TOPIC TAGS: rare-earth metal, physical property, chemical property, rare-earth metal production, rare-earth metal refining, rare-earth metal alloy, alloy, rare-earth metal phase diagram, phase diagram, rare-earth metal crystal structure, crystal structure, rare-earth metal physical property, rare-earth metal chemical property

ABSTRACT: At the Soveshchaniye po "Novym napravleniyam v issledovanii i primenenii reikozemel'nykh metallov" (Conference on "New Directions in the Study and Applications of Rare-Earth Metals"), held at the Institut metallurgii im. A. A. Baykova (Institute of Metallurgy) in Moscow, 18-20 March 1963, and attended by 510 representatives of 95 organizations from 25 cities of the Soviet Union, 53 reports were presented which dealt with the physicochemical properties of

ACCESSION NR: AP3002396

14

rare-earth metals, methods of production and refining of rare-earth metals, rare-earth metals and their alloys, phase diagrams, crystal structures, and use of rare-earth metals in making steels and alloys. In his introduction, M. V. Pridantsev, chairman of the organization committee, noted the large-scale work conducted in the Soviet Union on production, study of properties, and use of rare-earth metals and their alloys. Speaking on the present status and problems in further studies of alloys of rare-earth metals, Ye. M. Savitskiy stressed the beneficial effect of rare-earth metals on the structure and physical, mechanical, and other properties of alloys of almost all metals and outlined the most important problems in the scientific research on rare-earth metals and their alloys. V. F. Lerekhova reported on the main achievements in the study of physicochemical properties, development of methods of refining rare-earth metals (zone refining, distillation), single-crystal growing, and plotting phase diagrams of rare-earth metals with the elements of all groups of the periodic table. K. P. Balov, V. I. Chichernikov, and N. V. Vol'kenshteyn spoke on magnetic and electric properties of rare-earth metals and their alloys. V. L. Levshin described the use of rare-earth metals as activators of fluorescent lamps. B. V. Bondarenko spoke on the use of rare-earth metals for thermionic cathodes. Special properties of scandium, its oxidation, and its use as a getter were discussed by O. P. Neumkin. Phase diagrams of Gd rare-earth metal alloys were described by

1. V. Burov, and of Y rare-earth metal alloys, by I. A. Markova. Yu. F. Yefimov spoke on the effect of rare-earth metals on the ductility of vanadium. V. A. Frolov, on the ductility of molybdenum. Reports of Ye. I. Gladyshevskiy, P. I. Kripyakevich, O. S. Zaruchnyuk, V. I. Yevdokimenko, and V. V. Tsvetkov on the physical and mechanical properties of rare-earth metal alloys.

2. V. A. Kuznetsov spoke on the physical properties and prospects for the application of refractory compounds. Yu. B. Koyakovsky and A. F. Vichkarev reported on the use of rare-earth metals for improving steel properties and on the deoxidizing properties of rare-earth metals and their effect on the nature of inclusions. Two reports by V. S. Vvedenskiy dealt with the effect of rare-earth metals on the properties of stainless and structural steel. V. F. Popov described the beneficial effect of Ce in melting Kh18Ni12M2T [AISI 316T] stainless steel. A. A. Prepyakov spoke on the beneficial effect of Ce on the ductility of brass. T. M. Slutskaya, on the structure and mechanical properties of welded joints, and V. P. Taratynov, on improvement of the physical and mechanical properties of Fe-base, Co-base, or Ni-base alloys. The conference recommended intensification of research in the field, establishment of a new monthly periodical, *Redkiye metally* (Rare Metals), and calling the next conference on rare-earth metals in 1955.

TITLE: Phase diagram and the properties of alloys of the aluminum-scandium system

SOURCE: AN SSSR. Izvestiya. Metally, no. 4, 1965, 176-182

TOPIC TAGS: aluminum, scandium, aluminum scandium alloy, aluminum scandium system

ABSTRACT: A large series of aluminum-scandium alloys melted from 98.16- or 99.5%-pure Sc and 99.99%-pure Al has been studied. On the basis of the results obtained, a phase diagram of the Al-Sc system (see Fig. 1 of the Enclosure) was plotted. The investigations showed that Al and Sc have unlimited solubility in the liquid state. The room-temperature solubility of Sc in Al is approximately 0.5 at% and that of Al in Sc approximately 4 at%. Four compounds:  $ScAl_3$ ,  $ScAl_2$ ,  $ScAl$ , and  $Sc_2Al$  were identified. All the compounds are brittle and crack during solidification. The microhardness is 255, 530, 370, and 460 kg/mm. for  $ScAl_3$ ,  $ScAl_2$ ,

Card 1/4

ScAl<sub>1</sub> and Sc<sub>2</sub>Al, respectively. Alloying with Sc increases the tensile strength at room and elevated temperatures without a noticeable decrease in ductility (see Fig. 2 of the Enclosure). The strengthening effect of Sc is much stronger than that of rare-earth metals. Orig. art. has: 6 figures and 1 table. [WW]

TITLE: Calorizing nickel-base alloys  
19 44,55, 21

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 10, 1965, 32-34

TOPIC TAGS: steel, alloy steel, heat resistant steel, steel calorizing, calorized steel mechanical property, steel oxidation resistance/EI867 steel, EI929 steel, ZhS6K steelABSTRACT: EI867, EI929, and ZhS6K heat-resistant alloys were calorized in a mixture consisting of 98% ferroaluminum master alloy and 2% ammonium chloride at 850—1110°C for 2, 4, and 8 hr in order to determine the effect of the temperature, and duration of exposure on the depth of the surface layer and on the structure, heat resistance, and mechanical properties of the alloys. The weight gain per unit surface, the calorized layer depth, and the rate of calorizing were found to increase with increasing temperature of calorizing. With increasing exposure time, the depth and the weight gain of the calorized layer increased at a parabolic rate. With increasing time of exposure at a constant temperature, the layer depth and weight gain increased, but the rate of calorizing decreased. The surface layer on EI867 and ZhS6K alloys calorized at 950°C for 4 hr contained 37—40% Al at a depth of 15  $\mu$ . The

Card 1/2

L 6484-66

ACC NR: AP5025596

calorized layer on all alloys consisted of an outer zone with a microhardness of 700-850 and an inner, thinner zone with a microhardness of 700-600, compared with 400-350 for the base metal. Annealing at 750C for 2 and 5 hr decreased the microhardness of the outer zone from 770 to 600 and 500, respectively, but had no effect on the hardness of the inner zone. Calorizing at 950C for 4 hr had no effect on the tensile, rupture, and fatigue strengths and ductility characteristics of the alloys at room and elevated temperatures, but significantly increased their oxidation resistance at 1000C. The oxidation resistance of the alloys did not depend on the temperature and duration of calorizing. This makes it possible to calorize heat-resistant nickel-base alloys at various temperatures and to combine calorizing with heat treatment. Orig. art. has: 4 figures. [MS]

Atlas of Spectral Lines for a Spectrograph with Diffraction Grating

Brestov, Academician NIK. S. Zembla, Institute of Spectroscopy, 1959.  
Vol. 2, pp. 9, 27, 1061-1063 (1959)

**ABSTRACT:**  
 In connection with the series production of diffraction grating spectographs, the necessity of additional identification of the elements in polished rods, as well as the preparation of a table of spectral lines for creating a spectrograph, an atlas of spectral lines (plasma) and of their intensities is being prepared. The table consists of plane tables (plasma) and of their descriptions. In Figure 1, for example, the iron spectrum is shown. In Figure 6, for example, the iron spectrum is recorded in a range extending over 60 °C. The gratings, the gratings of which are by means of the DPG-3 spectrograph, the gratings of which have 500 gratings and the length of the plane table is about 20 cm, and the total length of the iron spectrum is 570 mm, or 1/3 of the table. Owing to the high dispersion of the total length of 175 m, only 100 lines of the elements are recorded, and the intensity of the lines is estimated according to a 12-degree scale.

If the sample contains more than 10% of the element, the lines are marked by the figure 12, and if it contains less than 0.001%, by the figure 12. In the description the properties of the lines are discussed, and directives are given for carrying out analyses. There are 1 figure and 3 general references.

TITLE: Determination of the Filtration Coefficient in Clean  
Sands by the Method of the Ukrainian Highway Scientific  
Research Institute (Opredeleniye koeffitsiyenta fil'-  
tratsii chistiykh peskov metodom UkrdorNII)

PERIODICAL: Sb. tr. Ukr. dor-transp. n.-i. in-ta, 1955, Nr 1,  
pp 3-18

ABSTRACT: The author considers the method and the apparatus for  
determining the filtration coefficient for a number of  
sands according to the technique developed in the labo-  
ratories of the Ukrainian Highway Scientific Research  
Institute in 1949 by P. N. Kovalev. The method con-  
sists basically of standardizing a preparation of the  
sample and compacting it to its greatest density,

Card 1/2

Determination of the Filtration Coefficient in Clean Sands (Cont.) 15-57-1-1040

corresponding to the density under natural conditions in highway surfacing. The proposed apparatus is called a filtration meter. It permits the determination of the filtration coefficient in sands both with disturbed and with undisturbed structures. Information is given on the construction and the calculations of the apparatus, on the technique of using it, and on the results of studies on samples with disturbed and undisturbed structures. The author concludes by commenting on the considerable advantages in the proposed method and apparatus as compared with the generally used method of Geynikh according to the All-Union State Standard 3587-47, namely: 1) the short time for testing (10 to 15 minutes); 2) the possibility of measuring the filtration coefficient in sands with disturbed and undisturbed structures directly in the field; 3) the simplicity in handling and preparation; 4) the small size and light weight.

TITLE: Luminescence of chlorophyll excited by a ruby laser

SOURCE: AN SSSR. Doklady, v. 168, no. 1, 1966, 68-71

TOPIC TAGS: luminescence, luminescence spectrum, luminescent material, laser application, laser effect, chlorophyll

ABSTRACT: Experiments were performed to detect radiation emission during transition of a molecule from the second excited singlet level to the ground level ( $S_2^* \rightarrow S_0$ ). A high-power ruby laser (J. L. Hall et al., Phys. Rev. Lett., 11, 364 (1963); W. L. Peticolas, et al., Phys. Rev. Lett., 10, 43, (1963); J. B. Birks et al., Phys. Lett., 18, 127 (1965) was used to excite solution of chlorophyll "a" ( $5 \times 10^{-3}$  M), methyl-chlorophyllide ( $5 \times 10^{-3}$  M), magnesium phthalocyanine ( $10^{-4}$  M) in ethyl alcohol, chlorophylline ( $5 \times 10^{-3}$  M) in methyl alcohol, and phthalocyanine without metal ( $10^{-4}$  M) in dioxane. The emission from a "Razdan" K-4-2 laser (pulse energy of 1 joule, with a pulse repetition frequency of 2 cps) was focused on the object by a lens through a KS-17 light filter. The luminescence of the object was separated by means of a ZMR-3 monochromator (linear dispersion in the investigated range was

Card 1/2

ACC NR: AP6015085

0

20  $\mu\text{m}$ ). The photon counting method was used for recording the luminescence spectrum. A blue-green luminescence in the path of the laser beam was clearly seen in the solutions of chlorophyll "a" and methylchlorophyllide. The spectrum of this luminescence at 290K displayed a 430—510  $\mu\text{m}$  band with a maximum at 480  $\mu\text{m}$  displaced to the longwave side with respect to the 430  $\mu\text{m}$  band of the absorption spectrum. The observed band can be attributed to the expected radiative transition from the  $S_2^*$  level to the  $S_0$  ground level. Three processes are suggested as possible causes for the excitation of the molecule to a high  $S_2^*$  level during absorption of small-energy photons: 1) addition of two photons of a powerful pulse owing to an intermediate virtual level; 2) two-photon excitation resulting from the first excited singlet state during its existence ( $2 \times 10^{-9}$  sec); and 3) accumulation, caused by a powerful pulse, of a high concentration of triplet molecules with subsequent triplet-triplet annihilation. Orig. art. has: 2 figures. [JA]

Photodissociation of salt molecules into ions. A. TERRIN AND B. PONOV. *Physik Z. Sowjetunion* 2, 299-314 (1932) — Measurements of the wave length for max. photo dissociation were carried out for TlI, TlBr and TlCl. The values found were 213 mp for TlI, 201 mp for TlBr, and 185 mp for TlCl. The potential-energy curves for the binding energy of the mol. TlI for the normal and ionic state are given. In contrast to the behavior of the alkali halides in the presence of light where the mol. are in the normal ionic state and are transformed by light absorption to the  $\alpha$ -type of binding with resulting dissociation, the TlI mol. changes from the normal to the ionic state followed by dissociation.

J. H. Wren

The effective cross section for the recombination of atoms with emission of radiation. A. TIRANIN AND N. PANDHARYA. *Physik. Z. Sowjetunion* 2, 317 (1947). A general relation between the velocity const. of photoionization and recombination according to the scheme  $h\nu + AB \rightleftharpoons A' + B$  is advanced. These const. are  $k_0$  for the direct process and  $k_1$  for the reverse. This relation  $k_0/k_1 = (8\pi^2 \mu^2 h^2 g' g^2 \tau^2 = (8\pi^2 \mu^2 h^2 g' g^2 \tau^2) (p^2/g^2 \lambda^2)^2$  allows the effective cross section of the atom for interaction with radiation to be calculated from the absorption coeff. and the reverse.  $g'$  and  $g$  are quantum no.s for the excited and non-excited states,  $\tau$  is the symmetry no., and the other symbols have their usual significances. On the basis of present data, the formation of a mol. from atoms with radiation of energy has been calculated to have a very small probability ( $10^{-4} - 10^{-5}$ ). C. E. P. TIRANIN

Amision bands excited in thallium iodide vapor by ultra-violet light. A. Tepenskij  
Physik. Z. Sowjetunion 2, 377-40 (1932).-- New emission bands were found on exciting  
TlI vapor with light of wave length of 2100-1850 Å. U. of the following types: 3144-  
2020 Å. U. excites 2 sharply enhanced maxima at 4084 and 4004 Å. U. with adjoining  
weaker maxima belonging to the complete absorption band spectrum of TlI mols.,  
and an apparently continuous band with a sharp edge at 3425 Å. U. stretching toward  
shorter wave lengths. Excitation by  $\lambda$  1903-1854 Å. U. gives rise to a continuous spec-  
trum from 4000 to 5000 Å. U. with a band at 4152 Å. U. belonging to the system of  
maxima in the absorption spectrum of TlI, and a narrow band at 3475 Å. U. The  
origins of these spectra are discussed. C. E. P. TEFERKIS

Photophysical reactions of adsorbed iodine molecules  
A. Tsvetan, *Acta Physicochim. (U. S. S. R.)*, 17, 178-80  
(1934).—Adsorbed I<sub>2</sub> mols. are dissolved, but not desorbed  
by the action of light. The dissolved adsorbed I<sub>2</sub> can re-  
act with unsaturated substances, such as the H<sup>+</sup> ion when  
bromous iodide is used as the adsorbing crystal lattice.  
The brown color of the I<sub>2</sub> mols. gradually disappears,  
light of 3600 Å, being most effective. The effect is not  
observed on a CsI adsorbed lattice. It also reacts with  
a max. at 4300 Å, while O reacts for excitation by all  
visible light. J. H. Rathmann

"Interpol" recombination during reassociation of polyribonucleic molecules. J. N. Tamm (Chem. Revs., Amer. Chem. Union, 1954, 54, 1629-1657).—On reassociation of RNA, reported as  $10^{-10} \text{ sec}^{-1}$  at  $25^\circ\text{C}$ ,  $10^{-10} \text{ sec}^{-1}$  at  $37^\circ\text{C}$ , and  $10^{-10} \text{ sec}^{-1}$  at  $45^\circ\text{C}$ , a reassociation spectrum with a peak at 3400-3500 Å, a fluorescence spectrum of  $\text{K}^+$  was observed, indicating that  $\text{K}^+$  is chelated with RNA in contact. The process has a matched triplet state, resonance, and reactivation energy. The photochemical recombination of  $\text{K}^+$  has above a fluorescence, and may be due to the formation of a chelating ring with  $\text{K}^+$ . J. H. 1

Fluorescence of salts surface-activated by condensed metals. A. TEKIN and F. CLEMENT (Acta Physicochim. U.R.S.S., 1934, 1, 941-960). A bright visible fluorescence is obtained from alkali halides in ultra-violet light after Cu, Ti, Pb, Bi, or Cd is condensed in *vac.* on them. The emission consists of broad bands and is excited by  $\lambda < 3000 \text{ \AA}$ . No fluorescence was observed with Na on alkali halides, or when the latter are replaced by  $\text{AgCl}$ ,  $\text{AgI}$ , or  $\text{Cu}_2\text{Cl}_3$ . The most intense effects were with  $\text{NaBr}$ ,  $\text{Ti}$  (blue),  $\text{NaI}$ ,  $\text{Cu}$ ,  $\text{Ti}$ ,  $\text{Pb}$ , or  $\text{Bi}$  (all violet),  $\text{Cd}$ ,  $\text{Sn}$ , or  $\text{Ti}$  (yellow), and  $\text{Pb}$  (green).

absorptive cross section in the recombination of atoms on  
irradiation. A. N. Terent'ev and N. A. Prikharchuk. J.  
Phys. Chem. (U.S.S.R.) 3, 1034 (1934). For the  
photodissociation-recombination reaction  $A + B \rightleftharpoons A' + B'$  the  
equations  $\sigma_r / K_r = (h\sigma^2 / \pi m^2 I^2) f f' \gamma$  and  $\sigma^2 =$   
( $h\sigma^2 / \pi m^2 I^2 \gamma^2 / \lambda^2 (f/f')^2$ ) are given for the values of the  
const. of the equil. equation ( $K_r$  is the coeff. of mol.  
absorption for the forward process and  $\sigma_r$  the effective  
cross section for the reverse,  $m$  is the reduced mass of  $A +$   
 $B$ ,  $f$  and  $f'$  are the statistical wts. of excited and normal  
atoms,  $I$  is the light intensity and  $\gamma$  the symmetry of the  
mol.). On the basis of known data for the absorption coeff.,  
the recombination of a diat. mol. from the atoms formed  
by photodissocn. has a probability of the order  $\gamma = 10^{-4}$   
to  $10^{-5}$ . In particular the cases of Cl, Br, I, Cl and  
NaI are discussed.  
Runo Hanninen

Elementary processes accompanying chemical reactions  
A. N. Tersoff. *Trans. VI. Mendeleev Congr. Theor. Applied Chem.* 1932 2, Pt. 1, 75 (1936). The development of every reaction can be dismembered into a series of reactions of the simplest type: (1) formation of a diatomic mol.:  $A + B \rightarrow AB$ , (2) decompos. of a diatomic mol.:  $AB \rightarrow A + B$ , (3) exchange reaction:  $A + BC \rightarrow AB + C$ . The kinetic processes taking place in each case are elucidated in detail. R. E. S.

Decomposition of polyatomic molecules by Schumann radiation. G. G. NURKIN and A. N. Tsvetkov (Bull. Acad. Sci. U.R.S.S., 1936, 559-565).—The fluorescence under the action of Schumann radiation of a no. of compounds in the vapor state has been investigated.  $I_2$  emits the line 2003 Å. of at. I.  $TlCl$  emits the spectrum of at. Tl.  $H_2O$ ,  $MeOH$ ,  $KOH$ ,  $HCO_3H$ , and  $AcOH$  emit bands of the OH radical.  $MeCl$  emits the CN bands.  $NH_3$  and  $N_2H_4$  emit the  $\pi$ -bands of  $NH_4$ ; this emission is ascribed to an excited  $NH_3$  radical. Band emissions in the visible were observed with  $CO$  and  $HCO_2H$ , the latter being ascribed to the  $NCO$  radical. The emission of the excited OH radical is quenched strongly by  $CO$  and  $H_2$ .  $N_2$  and  $A$  have little effect. The emission of the CN radical is quenched by  $N_2$ , the quenching of the 0-0 band being > that of the band I-I. The emission of the  $NH_3$  radical is approx. equally quenched by  $N_2$ ,  $H_2$ , and  $A$ . O. D. S.
